```

Before we begin investigating the several theories we wish to consider, we present a general theory of syntax and capture-avoiding substitution.

A *taxonomy* consists of:

- a set of *expression kinds*;
- a subset of expression kinds, called the *variable kinds*. We refer to the other expression kinds as *non-variable kinds*.

A *grammar* over a taxonomy consists of:

- a set of *constructors*, each with an associated *constructor kind* of the form

$$((A_{11}, \dots, A_{1r_1})B_1, \dots, (A_{m1}, \dots, A_{mr_m})B_m)C \quad (1)$$

where each A_{ij} is a variable kind, and each B_i and C is an expression kind.

- a function assigning, to each variable kind K , an expression kind, the *parent* of K .

A constructor c of kind (1) is a constructor that takes m arguments of kind B_1, \dots, B_m , and binds r_i variables in its i th argument of kind A_{ij} , producing an expression of kind C . We write this expression as

$$c([x_{11}, \dots, x_{1r_1}]E_1, \dots, [x_{m1}, \dots, x_{mr_m}]E_m) . \quad (2)$$

The subexpressions of the form $[x_{i1}, \dots, x_{ir_i}]E_i$ shall be called *abstractions*, and the pieces of syntax of the form $(A_{i1}, \dots, A_{ij})B_i$ that occur in constructor kinds shall be called *abstraction kinds*.

We formalise this as follows. First, we construct the sets of expression kinds, constructor kinds and abstraction kinds over a taxonomy:

```

record Taxonomy : Set1 where
  field
    VarKind : Set
    NonVarKind : Set

data ExpressionKind : Set where
  varKind : VarKind → ExpressionKind
  nonVarKind : NonVarKind → ExpressionKind

data KindClass : Set where
  -Expression : KindClass
  -Abstraction : KindClass

```

-Constructor : ExpressionKind → KindClass

```
data Kind : KindClass → Set where
  base : ExpressionKind → Kind -Expression
  out  : ExpressionKind → Kind -Abstraction
  Π    : VarKind → Kind -Abstraction → Kind -Abstraction
  out2 : ∀ {K} → Kind (-Constructor K)
  Π2   : ∀ {K} → Kind -Abstraction → Kind (-Constructor K) → Kind (-Constructor K)
```

An *alphabet* A consists of a finite set of *variables*, to each of which is assigned a variable kind K . Let \emptyset be the empty alphabet, and (A, K) be the result of extending the alphabet A with one fresh variable x_0 of kind K . We write $\text{Var } A \ K$ for the set of all variables in A of kind K .

```
data Alphabet : Set where
  ∅ : Alphabet
  _,_ : Alphabet → VarKind → Alphabet

data Var : Alphabet → VarKind → Set where
  x0 : ∀ {V} {K} → Var (V , K) K
  ↑ : ∀ {V} {K} {L} → Var V L → Var (V , K) L
```

We can now define a grammar over a taxonomy:

```
record ToGrammar : Set1 where
  field
    Constructor : ∀ {K} → Kind (-Constructor K) → Set
    parent      : VarKind → ExpressionKind
```

The *expressions* of kind E over the alphabet V are defined inductively by:

- Every variable of kind E is an expression of kind E .
- If c is a constructor of kind (1), each E_i is an expression of kind B_i , and each x_{ij} is a variable of kind A_{ij} , then (2) is an expression of kind C .

Each x_{ij} is bound within E_i in the expression (2). We identify expressions up to α -conversion.

```
data Subexpression : Alphabet → ∀ C → Kind C → Set
Expression : Alphabet → ExpressionKind → Set
Body : Alphabet → ∀ {K} → Kind (-Constructor K) → Set
Abstraction : Alphabet → Kind -Abstraction → Set
```

```
Expression V K = Subexpression V -Expression (base K)
Body V {K} C = Subexpression V (-Constructor K) C
```

```
alpha : Alphabet → Kind -Abstraction → Alphabet
```

```

alpha V (out _) = V
alpha V (Π K A) = alpha (V , K) A

beta : Kind -> Abstraction -> ExpressionKind
beta (out K) = K
beta (Π _ A) = beta A

Abstraction V A = Expression (alpha V A) (beta A)

data Subexpression where
  var : ∀ {V} {K} → Var V K → Expression V (varKind K)
  app : ∀ {V} {K} {C} → Constructor C → Body V {K} C → Expression V K
  out2 : ∀ {V} {K} → Body V {K} out2
  app2 : ∀ {V} {K} {A} {C} → Abstraction V A → Body V {K} C → Body V (Π2 A C)

var-inj : ∀ {V} {K} {x y : Var V K} → var x ≡ var y → x ≡ y
var-inj refl = refl

```

2.1 Families of Operations

We now wish to define the operations of *replacement* (replacing one variable with another) and *substitution* of expressions for variables. To this end, we define the following.

A *family of operations* consists of the following data:

- Given alphabets U and V , a set of *operations* $\sigma : U \rightarrow V$.
- Given an operation $\sigma : U \rightarrow V$ and a variable x in U of kind K , an expression $\sigma(x)$ over V of kind K , the result of *applying* σ to x .
- For every alphabet V , an operation $\text{id}_V : V \rightarrow V$, the *identity* operation.
- For any operations $\rho : U \rightarrow V$ and $\sigma : V \rightarrow W$, an operation $\sigma \circ \rho : U \rightarrow W$, the *composite* of σ and ρ .
- For every alphabet V and variable kind K , an operation $\uparrow : V \rightarrow (V, K)$, the *successor* operation.
- For every operation $\sigma : U \rightarrow V$, an operation $(\sigma, K) : (U, K) \rightarrow (V, K)$, the result of *lifting* σ . We write $(\sigma, K_1, K_2, \dots, K_n)$ for $((\dots (\sigma, K_1), K_2), \dots), K_n)$.

such that

1. $\uparrow(x) \equiv x$
2. $\text{id}_V(x) \equiv x$
3. $(\sigma \circ \rho)(x) \equiv \sigma[\rho(x)]$
4. Given $\sigma : U \rightarrow V$ and $x \in U$, we have $(\sigma, K)(x) \equiv \sigma(x)$

5. $(\sigma, K)(x_0) \equiv x_0$

where, given an operation $\sigma : U \rightarrow V$ and expression E over U , the expression $\sigma[E]$ over V is defined by

$$\sigma[x] \stackrel{\text{def}}{=} \sigma(x) \sigma[c([x_{11}, \dots, x_{1r_1}]E_1, \dots, [x_{n1}, \dots, x_{nr_n}]E_n)] \stackrel{\text{def}}{=} c([x_{11}, \dots, x_{1r_1}](\sigma, K_{11}, \dots, K_{1r_1})[E_1], \dots, [x_{n1}, \dots, x_{nr_n}](\sigma, K_{n1}, \dots, K_{nr_n})[E_n])$$

where K_{ij} is the kind of x_{ij} .

We say two operations $\rho, \sigma : U \rightarrow V$ are *equivalent*, $\rho \sim \sigma$, iff $\rho(x) \equiv \sigma(x)$ for all x . Note that this is equivalent to $\rho[E] \equiv \sigma[E]$ for all E .

The alphabets and operations up to equivalence form a category, which we denote **Op**. The action of application associates, with every operator family, a functor **Op** → **Set**, which maps an alphabet U to the set of expressions over U , and every operation σ to the function $\sigma[-]$. This functor is faithful and injective on objects, and so **Op** can be seen as a subcategory of **Set**.

2.2 Replacement

The operation family of *replacement* is defined as follows. A replacement $\rho : U \rightarrow V$ is a function that maps every variable in U to a variable in V of the same kind. Application, idOpentity and composition are simply function application, the idOpentity function and function composition. The successor is the canonical injection $V \rightarrow (V, K)$, and (σ, K) is the extension of σ that maps x_0 to x_0 .

This providOpes us with the canonical mapping from an expression over V to an expression over (V, K) :

```

liftE : ∀ {V} {K} {L} → Expression V L → Expression (V , K) L
liftE E = E ⟨ upRep ⟩
--TODO Inline this

```

2.3 Substitution

A *substitution* σ from alphabet U to alphabet V , $\sigma : U \Rightarrow V$, is a function σ that maps every variable x of kind K in U to an *expression* $\sigma(x)$ of kind K over V . We now aim to prov that the substitutions form a family of operations, with application and idOpentity being simply function application and idOpentity.

```

Sub : Alphabet → Alphabet → Set
Sub U V = ∀ K → Var U K → Expression V (varKind K)

```

```

idOpSub : ∀ V → Sub V V
idOpSub _ _ = var

```

The *successor* substitution $V \rightarrow (V, K)$ maps a variable x to itself.

```

Sub↑ : ∀ {U} {V} {K} → Sub U V → Sub (U , K) (V , K)
Sub↑ _ _ x0 = var x0
Sub↑ σ K (↑ x) = (σ K x) ⟨ upRep ⟩

```

```

pre-substitution : PreOpFamily
pre-substitution = record {
  Op = Sub;
  apV = λ σ x → σ _ x;
  up = λ _ x → var (↑ x);
  apV-up = refl;
  idOp = λ _ _ → var;
  apV-idOp = λ _ → refl }

```

```

_~_ : ∀ {U} {V} → Sub U V → Sub U V → Set
_~_ = PreOpFamily._~op_ pre-substitution

```

```

Sub↑-cong : ∀ {U} {V} {K} {σ σ' : Sub U V} → σ ~ σ' → Sub↑ {K = K} σ ~ Sub↑ σ'
Sub↑-cong {K = K} σ-is-σ' x0 = refl
Sub↑-cong σ-is-σ' (↑ x) = cong (λ E → E ⟨ upRep ⟩) (σ-is-σ' x)

```

```

proto-substitution : LiftFamily
proto-substitution = record {
  preOpFamily = pre-substitution;
  isLiftFamily = record {
    liftOp = λ _ → Sub↑;
    liftOp-cong = Sub↑-cong }
}

```

Then, given an expression E of kind K over U , we write $E[\sigma]$ for the application of σ to E , which is the result of substituting $\sigma(x)$ for x for each variable in E , avoidOping capture.

```

2.5 Contexts

A *context* has the form $x_1 : A_1, \dots, x_n : A_n$ where, for each i :

- x_i is a variable of kind K_i distinct from x_1, \dots, x_{i-1} ;
- A_i is an expression of some kind L_i ;
- L_i is a parent of K_i .

The *domain* of this context is the alphabet $\{x_1, \dots, x_n\}$.

We give ourselves the following operations. Given an alphabet A and finite set F , let $\text{extend } A \text{ } K \text{ } F$ be the alphabet $A \uplus F$, where each element of F has kind K . Let embedr be the canonical injection $F \rightarrow \text{extend } A \text{ } K \text{ } F$; thus, for all $x \in F$, we have $\text{embedr } x$ is a variable of $\text{extend } A \text{ } K \text{ } F$ of kind K .

```

extend : Alphabet  $\rightarrow$  VarKind  $\rightarrow$   $\mathbb{N} \rightarrow$  Alphabet
extend A K zero = A
extend A K (suc F) = extend A K F , K

embedr :  $\forall \{A\} \{K\} \{F\} \rightarrow \text{Fin } F \rightarrow \text{Var } (\text{extend } A \text{ } K \text{ } F) \text{ } K$ 
embedr zero = x0
embedr (suc x) =  $\uparrow$  (embedr x)

```

Let `embed1` be the canonical injection $A \rightarrow \text{extend } A \ K \ F$, which is a replacement.

```

3 Propositional Logic

Fix sets of *proof variables* and *term variables*.

The syntax of the system is given by the following grammar.

$$\begin{array}{lll}
\text{Proof} & \delta & ::= p \mid \delta\delta \mid \lambda p : \phi.\delta \\
\text{Proposition} & f & ::= \perp \mid \phi \rightarrow \phi \\
\text{Context} & \Gamma & ::= \langle \rangle \mid \Gamma, p : \phi \\
\text{Judgement} & \mathcal{J} & ::= \Gamma \vdash \delta : \phi
\end{array}$$

where p ranges over proof variables and x ranges over term variables. The variable p is bound within δ in the proof $\lambda p : \phi.\delta$, and the variable x is bound within M in the term $\lambda x : A.M$. We identify proofs and terms up to α -conversion.

4 Predicative Higher-Order Propositional Logic

Fix sets of *proof variables* and *term variables*.

The syntax of the system is given by the following grammar.

Proof	$\delta ::= p \mid \delta\delta \mid \lambda p : \phi. \delta$
Term	$M, \phi ::= x \mid \perp \mid MM \mid \lambda x : A. M \mid \phi \rightarrow \phi$
Type	$A ::= \Omega \mid A \rightarrow A$
Term Context	$\Gamma ::= \langle \rangle \mid \Gamma, x : A$
Proof Context	$\Delta ::= \langle \rangle \mid \Delta, p : \phi$
Judgement	$\mathcal{J} ::= \Gamma \text{ valid} \mid \Gamma \vdash M : A \mid \Gamma, \Delta \text{ valid} \mid \Gamma, \Delta \vdash \delta : \phi$

where p ranges over proof variables and x ranges over term variables. The variable p is bound within δ in the proof $\lambda p : \phi. \delta$, and the variable x is bound within M in the term $\lambda x : A. M$. We identify proofs and terms up to α -conversion.

In the implementation, we write **Term**(V) for the set of all terms with free variables a subset of V , where $V : \mathbf{FinSet}$.
