open import Data.Fin public using (Fin;zero;suc)
open import Prelims
```

Before we begin investigating the several theories we wish to consider, we present a general theory of syntax and capture-avoiding substitution.

A taxononmy consists of:

- a set of expression kinds;
- a subset of expression kinds, called the *variable kinds*. We refer to the other expession kinds as *non-variable kinds*.

A grammar over a taxonomy consists of:

• a set of constructors, each with an associated constructor kind of the form

$$((A_{11}, \dots, A_{1r_1})B_1, \dots, (A_{m1}, \dots, A_{mr_m})B_m)C$$
 (1)

where each A_{ij} is a variable kind, and each B_i and C is an expression kind.

ullet a function assigning, to each variable kind K, an expression kind, the parent of K.

A constructor c of kind (1) is a constructor that takes m arguments of kind B_1, \ldots, B_m , and binds r_i variables in its ith argument of kind A_{ij} , producing an expression of kind C. We write this expression as

$$c([x_{11}, \dots, x_{1r_1}]E_1, \dots, [x_{m1}, \dots, x_{mr_m}]E_m)$$
 (2)

The subexpressions of the form $[x_{i1}, \ldots, x_{ir_i}]E_i$ shall be called *abstractions*, and the pieces of syntax of the form $(A_{i1}, \ldots, A_{ij})B_i$ that occur in constructor kinds shall be called *abstraction kinds*.

We formalise this as follows. First, we construct the sets of expression kinds, constructor kinds and abstraction kinds over a taxonomy:

 $\hbox{record Taxonomy} \;:\; \hbox{Set}_1 \;\; \hbox{where}$

field

VarKind : Set
NonVarKind : Set

data ExpressionKind : Set where

 $varKind : VarKind \rightarrow ExpressionKind$

 ${\tt nonVarKind}$: ${\tt NonVarKind}$ o ExpressionKind

data KindClass : Set where
 -Expression : KindClass
 -Abstraction : KindClass

-Constructor : ExpressionKind ightarrow KindClass

data Kind : KindClass ightarrow Set where

 $\begin{array}{ll} \texttt{base} \; : \; \texttt{ExpressionKind} \; \to \; \texttt{Kind} \; \; \texttt{-Expression} \\ \texttt{out} \; \; : \; \texttt{ExpressionKind} \; \to \; \texttt{Kind} \; \; \texttt{-Abstraction} \\ \end{array}$

 Π : VarKind o Kind -Abstraction o Kind -Abstraction

 $\mathtt{out}_2: \ orall \ ext{K} \ o \ ext{Kind} \ ext{(-Constructor K)}$

 Π_2 : orall {K} o Kind -Abstraction o Kind (-Constructor K) o Kind (-Constructor K)

An alphabet A consists of a finite set of variables, to each of which is assigned a variable kind K. Let \emptyset be the empty alphabet, and (A, K) be the result of extending the alphabet A with one fresh variable x_0 of kind K. We write $\mathsf{Var}\ A\ K$ for the set of all variables in A of kind K.

```
data Alphabet : Set where \emptyset : Alphabet \rightarrow VarKind \rightarrow Alphabet data Var : Alphabet \rightarrow VarKind \rightarrow Set where x_0 : \forall {V} {K} \rightarrow Var (V , K) K \uparrow : \forall {V} {K} {L} \rightarrow Var V L \rightarrow Var (V , K) L
```

We can now define a grammar over a taxonomy:

```
record ToGrammar (T : Taxonomy) : \mathsf{Set}_1 where open Taxonomy T field  
Constructor : \forall {K} \to Kind (-Constructor K) \to Set parent : \mathsf{VarKind} \to \mathsf{ExpressionKind}
```

The expressions of kind E over the alphabet V are defined inductively by:

- Every variable of kind E is an expression of kind E.
- If c is a constructor of kind (1), each E_i is an expression of kind B_i , and each x_{ij} is a variable of kind A_{ij} , then (2) is an expression of kind C.

Each x_{ij} is bound within E_i in the expression (2). We identify expressions up to α -conversion.

2.1 Families of Operations

We now wish to define the operations of *replacement* (replacing one variable with another) and *substitution* of expressions for variables. To this end, we define the following.

A family of operations consists of the following data:

- Given alphabets U and V, a set of operations $\sigma: U \to V$.
- Given an operation $\sigma: U \to V$ and a variable x in U of kind K, an expression $\sigma(x)$ over V of kind K, the result of applying σ to x.
- For every alphabet V, an operation $id_V: V \to V$, the *identity* operation.
- For any operations $\rho: U \to V$ and $\sigma: V \to W$, an operation $\sigma \circ \rho: U \to W$, the *composite* of σ and ρ
- For every alphabet V and variable kind K, an operation $\uparrow: V \to (V, K)$, the *successor* operation.
- For every operation $\sigma: U \to V$, an operation $(\sigma, K): (U, K) \to (V, K)$, the result of *lifting* σ . We write $(\sigma, K_1, K_2, \dots, K_n)$ for $((\cdots (\sigma, K_1), K_2), \cdots), K_n)$.

such that

- 1. $\uparrow(x) \equiv x$
- 2. $id_V(x) \equiv x$
- 3. $(\sigma \circ \rho)(x) \equiv \sigma[\rho(x)]$
- 4. Given $\sigma: U \to V$ and $x \in U$, we have $(\sigma, K)(x) \equiv \sigma(x)$
- 5. $(\sigma, K)(x_0) \equiv x_0$

where, given an operation $\sigma: U \to V$ and expression E over U, the expression $\sigma[E]$ over V is defined by

 $\sigma[x] \stackrel{=}{\operatorname{def}} \sigma(x) \sigma[c([x_{11}, \dots, x_{1r_1}]E_1, \dots, [x_{n1}, \dots, x_{nr_n}]E_n)] \stackrel{=}{\operatorname{def}} c([x_{11}, \dots, x_{1r_1}](\sigma, K_{11}, \dots, K_{1r_1})[E_1], \dots, [x_{nr_n}]E_n)]$

where K_{ij} is the kind of x_{ij} .

We say two operations $\rho, \sigma: U \to V$ are equivalent, $\rho \sim \sigma$, iff $\rho(x) \equiv \sigma(x)$ for all x. Note that this is equivalent to $\rho[E] \equiv \sigma[E]$ for all E.

The alphabets and operations up to equivalence form a category, which we denote **Op**. The action of application associates, with every operator family, a functor $\mathbf{Op} \to \mathbf{Set}$, which maps an alphabet U to the set of expressions over U, and every operation σ to the function $\sigma[-]$. This functor is faithful and injective on objects, and so \mathbf{Op} can be seen as a subcategory of \mathbf{Set} .

2.2 Replacement

The operation family of replacement is defined as follows. A replacement $\rho: U \to V$ is a function that maps every variable in U to a variable in V of the same kind. Application, idOpentity and composition are simply function application, the idOpentity function and function composition. The successor is the canonical injection $V \to (V, K)$, and (σ, K) is the extension of σ that maps x_0 to x_0 .

```

2.3 Substitution

A substitution σ from alphabet U to alphabet V, $\sigma: U \Rightarrow V$, is a function σ that maps every variable x of kind K in U to an expression $\sigma(x)$ of kind K over V. We now aim to prove that the substitutions form a family of operations, with application and idOpentity being simply function application and idOpentity.

```
{\tt Sub} \; : \; {\tt Alphabet} \; \to \; {\tt Alphabet} \; \to \; {\tt Set}
Sub U V = \forall K \rightarrow Var U K \rightarrow Expression V (varKind K)
\mathtt{idOpSub} \;:\; \forall \;\; \mathtt{V} \;\to\; \mathtt{Sub} \;\; \mathtt{V} \;\; \mathtt{V}
idOpSub _ _ = var
 The successor substitution V \to (V, K) maps a variable x to itself.
\texttt{Sub}\uparrow : \forall {U} {V} {K} \rightarrow Sub U V \rightarrow Sub (U , K) (V , K)
Sub\uparrow \_ \_ x_0 = var x_0
Sub\uparrow \sigma K (\uparrow x) = liftE (\sigma K x)
pre-substitution : PreOpFamily
pre-substitution = record {
    Op = Sub;
    apV = \lambda \sigma x \rightarrow \sigma x;
    up = \lambda - x \rightarrow var (\uparrow x);
    apV-up = refl;
    idOp = \lambda _ _ \rightarrow var;
    apV-idOp = \lambda _ \rightarrow refl }
_~_ : \forall {U} {V} \rightarrow Sub U V \rightarrow Sub U V \rightarrow Set
_{\sim} = PreOpFamily._{\sim}op_ pre-substitution
\texttt{Sub}\uparrow\texttt{-cong} \;:\; \forall \; \{\texttt{U}\} \; \{\texttt{K}\} \; \{\texttt{\sigma} \; \texttt{\sigma'} \;:\; \texttt{Sub} \; \texttt{U} \; \texttt{V}\} \; \rightarrow \; \texttt{\sigma} \; \sim \; \texttt{\sigma'} \; \rightarrow \; \texttt{Sub}\uparrow \; \{\texttt{K} \; \texttt{=} \; \texttt{K}\} \; \texttt{\sigma} \; \sim \; \texttt{Sub}\uparrow \; \texttt{\sigma'}
Sub\uparrow-cong {K = K} \sigma-is-\sigma' x_0 = refl
Sub\uparrow-cong \sigma-is-\sigma' (\uparrow x) = cong liftE (\sigma-is-\sigma' x)
```

```
proto-substitution : LiftFamily
       proto-substitution = record {
               preOpFamily = pre-substitution;
                isLiftFamily = record {
                        liftOp = \lambda _ \rightarrow Sub\uparrow;
                        lift0p-x_0 = refl;
                        liftOp-cong = Sub\(\tau-cong\) }
               }
            Then, given an expression E of kind K over U, we write E[\sigma] for the appli-
cation of \sigma to E, which is the result of substituting \sigma(x) for x for each variable
in E, avoidOping capture.

2.4 Congruences

A congruence is a relation R on expressions such that:

```
1. if MRN, then M and N have the same kind;
```

```
2. if M_i R N_i for all i, then c[[\vec{x_1}]M_1, \dots, [\vec{x_n}]M_n]R c[[\vec{x_1}]N_1, \dots, [\vec{x_n}]N_n].
```

```
Relation : Set_1 Relation = \forall {V} {C} {K} \rightarrow Subexpression V C K \rightarrow Subexpression V C K \rightarrow Set
```

--TODO Abbreviations for Subexpression V (-Constructor... and Subexpression V -Abstracti record IsCongruence (R : Relation) : Set where field

2.5 Contexts

A context has the form $x_1:A_1,\ldots,x_n:A_n$ where, for each i:

- x_i is a variable of kind K_i distinct from x_1, \ldots, x_{i-1} ;
- A_i is an expression of some kind L_i ;
- L_i is a parent of K_i .

The domain of this context is the alphabet $\{x_1, \ldots, x_n\}$.

We give ourselves the following operations. Given an alphabet A and finite set F, let extend A K F be the alphabet $A \uplus F$, where each element of F has kind K. Let embedr be the canonical injection $F \to \mathsf{extend}\ A\ K\ F$; thus, for all $x \in F$, we have embedr x is a variable of extend A K F of kind K.

```
extend : Alphabet \to VarKind \to N \to Alphabet extend A K zero = A extend A K (suc F) = extend A K F , K
```

```
embedr : \forall {A} {K} {F} \rightarrow Fin F \rightarrow Var (extend A K F) K
  embedr zero = x_0
  embedr (suc x) = \uparrow (embedr x)
   Let embed be the canonical injection A \rightarrow extend A \times F, which is a re-
placement.
  \verb|embedl|: \forall \{A\} \{K\} \{F\} \rightarrow \texttt{Rep A (extend A K F)}|
  embedl \{F = zero\} _ x = x

3 Propositional Logic

Fix sets of proof variables and term variables.

The syntax of the system is given by the following grammar.

```
\begin{array}{lll} \text{Proof} & \delta & ::= & p \mid \delta\delta \mid \lambda p : \phi.\delta \\ \text{Proposition} & f & ::= & \bot \mid \phi \to \phi \\ \text{Context} & \Gamma & ::= & \langle \rangle \mid \Gamma, p : \phi \\ \text{Judgement} & \mathcal{J} & ::= & \Gamma \vdash \delta : \phi \end{array}
```

where p ranges over proof variables and x ranges over term variables. The variable p is bound within δ in the proof $\lambda p : \phi.\delta$, and the variable x is bound within M in the term $\lambda x : A.M$. We identify proofs and terms up to α -conversion.

4 Predicative Higher-Order Propositional Logic

Fix sets of proof variables and term variables.

The syntax of the system is given by the following grammar.

```
\begin{array}{lll} \text{Proof} & \delta & ::= & p \mid \delta\delta \mid \lambda p : \phi.\delta \\ \text{Term} & M, \phi & ::= & x \mid \bot \mid MM \mid \lambda x : A.M \mid \phi \rightarrow \phi \\ \text{Type} & A & ::= & \Omega \mid A \rightarrow A \\ \text{Term Context} & \Gamma & ::= & \langle \rangle \mid \Gamma, x : A \\ \text{Proof Context} & \Delta & ::= & \langle \rangle \mid \Delta, p : \phi \\ \text{Judgement} & \mathcal{J} & ::= & \Gamma \text{ valid } \mid \Gamma \vdash M : A \mid \Gamma, \Delta \text{ valid } \mid \Gamma, \Delta \vdash \delta : \phi \end{array}
```

where p ranges over proof variables and x ranges over term variables. The variable p is bound within δ in the proof $\lambda p: \phi.\delta$, and the variable x is bound within M in the term $\lambda x: A.M$. We identify proofs and terms up to α -conversion.

In the implementation, we write $\mathbf{Term}(V)$ for the set of all terms with free variables a subset of V, where $V : \mathbf{FinSet}$.
